# 6.170 Lecture 6
Procedure specifications

MIT EECS

Outline

Satisfying a specification; substitutability

Stronger and weaker specifications

    Comparing by hand

    Comparing via logical formulas

    Comparing via transition relations

Specification style; checking preconditions

Let P be an implementation and S a specification

P satisfies S **iff**

Every behavior of P is permitted by S
"The behavior of P is a subset of S"

The statement "P is correct" is meaningless

Though often made!

If P does not satisfy S, either (or both!) could be "wrong"

"One person's feature is another person's bug."
It's usually better to change the program than the spec

Example of a procedure specification

    // requires i > 0
    // modifies nothing
    // returns true iff i is a prime number
    public static boolean isPrime (int i)

General form of a procedure specification

    // requires
    // modifies
    // throws
    // effects
    // returns

Some set of procedures satisfies a specification

Suppose a procedure takes an integer as an argument

Spec 1: "returns an integer $\geq$ its argument"

Spec 2: "returns a non-negative integer $\geq$ its argument"

Spec 3: "returns argument + 1"

Spec 4: "returns argument^2"

Spec 5: "returns Integer.MAX_VALUE"

Consider these implementations

Code 1: `return arg * 2;`

Code 2: `return abs(arg);`

Code 3: `return arg + 5;`

Code 4: `return arg * arg;`

Code 5: `return Integer.MAX_VALUE;`

A stronger specification promises more

It constrains the implementation more

The client can make more assumptions

Substitutability

A stronger specification can always be substituted for a weaker one

Comparing specifications and procedures

We wish to compare procedures to specifications
>   Determine whether the procedure satisfies the specification
>   This indicates whether the implementer has succeeded

We wish to compare specifications to one another
>   Determine which specification (if either) is stronger
>   A procedure satisfying a stronger specification can be used
>>   anywhere that a weaker specification is required

Three ways to compare (use whichever is most convenient)
>   1.   By hand; examine each clause
>   2.   Logical formulas representing the specification
>   3.   Transition relations

We can weaken a specification by

Making <u>requires</u> harder to satisfy (strengthening <u>requires</u>)
  Preconditions: *contravariant*, all other clauses: *covariant*
Adding things to <u>modifies</u> clause (weakening <u>modifies</u>)
Making <u>effects</u> easier to satisfy (weakening <u>effects</u>)
Guaranteeing less about <u>throws</u> (weakening <u>throws</u>)
Guaranteeing less about <u>returns</u> value (weakening <u>returns</u>)

The strongest (most constraining) spec has the following:

<u>requires</u> clause: true
<u>modifies</u> clause: nothing
<u>effects</u> clause: false
<u>throws</u> clause: nothing
<u>returns</u> clause: false
(This particular spec is so strong as to be useless.)

Specification S1 is stronger than S2 iff:

$\forall$ P, (P satisfies S1) $\Rightarrow$ (P satisfies S2)

If each specification is a logical formula, this is equivalent to:

S1 $\Rightarrow$ S2

So, convert each spec to a formula (see following slides)

This specification:

// <u>requires</u> R
// <u>modifies</u> M
// <u>effects</u> E

is equivalent to this single logical formula:

$R \Rightarrow (E \land$ (nothing but M is modified))

What about <u>throws</u> and <u>returns</u>? Absorb them into <u>effects</u>.

Final result: S1 is stronger than S2 iff

$(R_1 \Rightarrow (E_1 \land \text{only-modifies-}M_1)) \Rightarrow (R_2 \Rightarrow (E_2 \land \text{only-modifies-}M_2))$

6.170 style:

requires (unchanged)
modifies (unchanged)
throws
effects   } correspond to resulting "effects"
returns

Example (from `java.util.ArrayList<T>`):

// requires: true
// modifies: this[index]
// throws: IndexOutOfBoundsException if index < 0 || index ≥ size()
// effects: this_{post}[index] = element
// returns: this_{pre}[index]
T set(int index, T element)

Equivalent spec, after absorbing <u>throws</u> and <u>returns</u> into <u>effects</u>:

// requires: true
// modifies: this[index]
// effects: if index < 0 || index ≥ size() then throws IndexOutOfBoundsException
//   else this_{post}[index] = element && returns this_{pre}[index]
T set(int index, T element)

Single logical formula

requires $\Rightarrow$ ((*not-modified*) $\wedge$ effects)

"not-modified" preserves every field not in <u>modifies</u> clause

Logical fact: If precondition is false, formula is true

Recall: $\forall x.\ x \Rightarrow true$; $\forall x.\ false \Rightarrow x$; $(x \Rightarrow y) \equiv (\neg x \vee y)$

Example:

// requires: true
// modifies: this[index]
// effects: E
`T set(int index, T element)`

Result:

true $\Rightarrow$ (($\forall i \neq index.\ this_{pre}[i] = this_{post}[i]$) $\wedge E$)

Transition relation relates prestates to poststates

Contains all possible ⟨input,output⟩ pairs

Transition relation maps procedure arguments to results

```
int increment(int i) {
  return i+1;
}

double mySqrt(double a) {
  if (Random.nextBoolean())
    return Math.sqrt(a);
  else
    return - Math.sqrt(a);
}
```

Specifications have transition relations, too

Contains just as much information as other forms of specification

A stronger specification has a smaller transition relation

Rule: P satisfies S iff P is a subset of S
   (when both are viewed as transition relations)

Sqrt specification (S_{sqrt})
>   // <u>requires</u> x is a perfect square
>   // <u>returns</u> positive or negative square root
>   int sqrt (int x)
>   Transition relation: $\langle 0,0 \rangle$, $\langle 1,1 \rangle$, $\langle 1,-1 \rangle$, $\langle 4,2 \rangle$, $\langle 4,-2 \rangle$, ...

Sqrt code (P_{sqrt})
>   int sqrt (int x) {
>   // ... always returns positive square root
>   }
>   Transition relation: $\langle 0,0 \rangle$, $\langle 1,1 \rangle$, $\langle 4,2 \rangle$, ...

P_{sqrt} satisfies S_{sqrt} because P_{sqrt} is a subset of S_{sqrt}

"P satisfies S iff P is a subset of S" is a good rule

But it gives the wrong answer for transition relations in abbreviated form
(The transition relations we have seen so far are in abbreviated form!)

anyOdd specification (S_{anyOdd})

// <u>requires</u> x = 0
// <u>returns</u> any odd integer
int anyOdd (int x)

Abbreviated transition relation: $\langle 0,1 \rangle, \langle 0,3 \rangle, \langle 0,5 \rangle, \langle 0,7 \rangle, \ldots$

anyOdd code (P_{anyOdd})

```
int anyOdd (int x) {
    return 3;
}
```

Transition relation: $\langle 0,3 \rangle, \langle 1,3 \rangle, \langle 2,3 \rangle, \langle 3,3 \rangle, \ldots$

The code satisfies the specification, but the rule says it does not

P_{anyOdd} is not a subset of S_{anyOdd}
because $\langle 1,3 \rangle$ is not in the specification's transition relation

We will see two solutions to this problem

Satisfaction via full transition relations (option 1)

The transition relation should make explicit everything an implementation may do

   Problem: abbreviated transition relation for S does not indicate all possibilities

anyOdd specification (S_{anyOdd}):   // same as before

   // <u>requires</u> x = 0
   // <u>returns</u> any odd integer
   int anyOdd (int x)
   Full transition relation: $\langle 0,1 \rangle$, $\langle 0,3 \rangle$, $\langle 0,5 \rangle$, $\langle 0,7 \rangle$, …   // on previous slide
   $\langle 1, 0 \rangle$, $\langle 1, 1 \rangle$, $\langle 1, 2 \rangle$, …, $\langle 1, exception \rangle$, $\langle 1, infinite\ loop \rangle$, …   // new
   $\langle 2, 0 \rangle$, $\langle 2, 1 \rangle$, $\langle 2, 2 \rangle$, …, $\langle 2, exception \rangle$, $\langle 2, infinite\ loop \rangle$, …   // new

anyOdd code (P_{anyOdd})   // same as before

```
int anyOdd (int x) {
    return 3;
}
```
   Transition relation: $\langle 0,3 \rangle$, $\langle 1,3 \rangle$, $\langle 2,3 \rangle$, $\langle 3,3 \rangle$, …   // same as before

The rule "P satisfies S iff P is a subset of S" gives the right answer for full relations

Downside: writing the full transition relation is bulky and inconvenient

   It's more convenient to make the implicit notational assumption:
      For elements not in the domain of S, any behavior is permitted.
      (Recall that a relation maps a *domain* to a *range*.)

Satisfaction via abbreviated transition relations(option 2)

New rule: P satisfies S iff P | (Domain of S) is a subset of S
> where "P | D" = "P restricted to the domain D"
>> i.e., remove from P all pairs whose first member is not in D
>> (recall that a relation maps a *domain* to a *range*)

anyOdd specification (S$_{anyOdd}$)
>> // <u>requires</u> x = 0
>> // <u>returns</u> any odd integer
>> int anyOdd (int x)
> **Abbreviated** transition relation: $\langle 0,1 \rangle$, $\langle 0,3 \rangle$, $\langle 0,5 \rangle$, $\langle 0,7 \rangle$, …

anyOdd code (P$_{anyOdd}$)
>> int anyOdd (int x) {
>>> return 3;
>> }
> Transition relation: $\langle 0,3 \rangle$, $\langle 1,3 \rangle$, $\langle 2,3 \rangle$, $\langle 3,3 \rangle$, …

Domain of S = { 0 }

P | (domain of S) = $\langle 0,3 \rangle$, which is a subset of S, so P satisfies S

The new rule gives the right answer even for abbreviated transition relations
> We'll use this version of the notation in 6.170

The abbreviated version of the transition relation can be misleading

    The true transition relation contains all the pairs

When doing comparisons

    Use the expanded transition relation, or
    Restrict the domain when comparing

Either approach makes the "smaller is stronger rule" work

Review: strength of a specification

A stronger specification is satisfied by fewer procedures

A stronger specification has
    weaker preconditions (note contravariance)
    stronger postcondition
    fewer modifications
    Advantage of this view: can be checked by hand

A stronger specification has a (logically) stronger formula
    Advantage of this view: mechanizable in tools

A stronger specification has a smaller transition relation
    Advantage of this view: captures intuition of "stronger =
    smaller" (fewer choices)

Specification style

Typically have only one of effects and returns

A procedure has a side effect or is called for its value
Exception: return old value, as for `HashMap.put`

The point of a specification is to be helpful

Formalism helps, overformalism doesn't

A specification should be

coherent (not too many cases)
informative (bad example: `HashMap.get`)
strong enough (to do something useful, to make guarantees)
weak enough (to permit (efficient) implementation)

Checking preconditions

- makes an implementation more robust
- provides better feedback to the client
- avoids silent errors

A quality implementation checks preconditions whenever it is *inexpensive* and *convenient* to do so
