Chapter 1: roadmap

1.1 What *is* the Internet?

1.2 Network edge

- end systems, access networks, links

1.3 Network core

- circuit switching, packet switching, network structure

1.4 Delay, loss and throughput in packet-switched networks

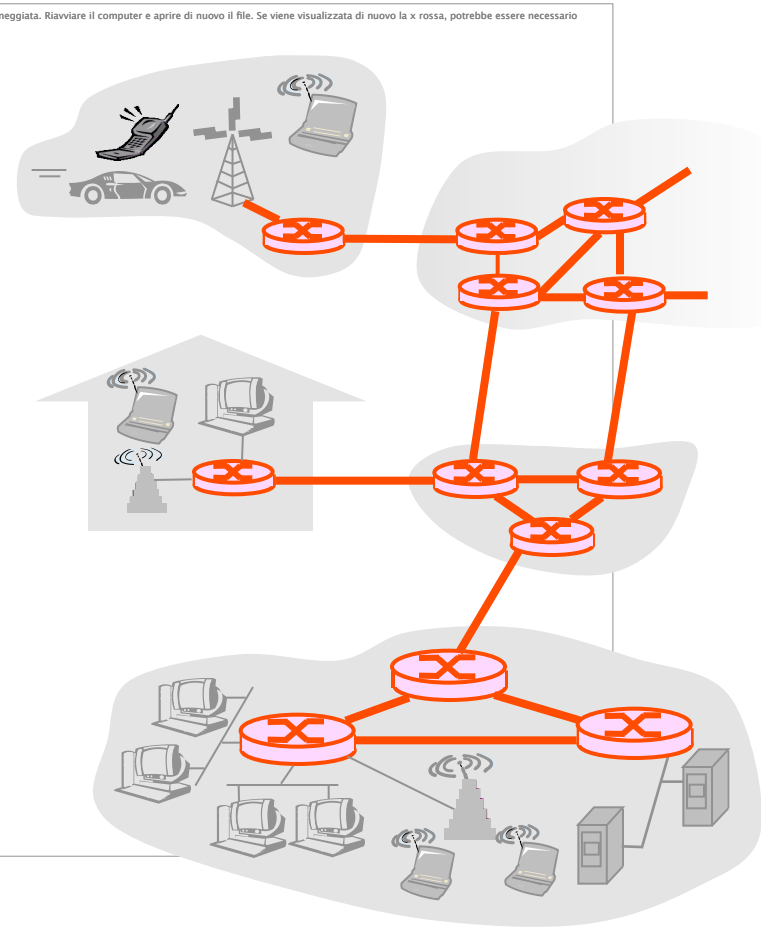

1.5 Protocol layers, service models

1.6 Networks under attack: security

1.7 History

The Network Core

- ❑ mesh of interconnected routers
- ❑ the fundamental question:
how is data transferred through net?
 - circuit switching:
dedicated circuit per call: telephone net
 - packet-switching: data sent thru net in discrete “chunks”

Network Core: Circuit Switching

End-end resources
reserved for “call”

- ❑ link bandwidth, switch capacity
- ❑ dedicated resources: no sharing
- ❑ circuit-like (guaranteed) performance
- ❑ call setup required

Network Core: Circuit Switching

network resources (e.g., bandwidth) **divided into “pieces”**

- pieces allocated to calls
- resource piece *idle* if not used by owning call (*no sharing*)

- dividing link bandwidth into “pieces”
 - ❖ frequency division
 - ❖ time division

Circuit Switching: FDM and TDM

FDM

Example:

4 users

TDM

Numerical example

- How long does it take to send a file of 640,000 bits from host A to host B over a circuit-switched network?
 - All links are 1.536 Mbps
 - Each link uses TDM with 24 slots/sec
 - 500 msec to establish end-to-end circuit

Let's work it out!

..Numerical example

- ❑ Each circuit has a transmission rate of $(1,536\text{Mbps})/24=64\text{Kbps}$
- ❑ $640000/64000=10\text{s}$
- ❑ Plus the circuit establishment $\rightarrow 10,5\text{s}$

Network Core: Packet Switching

each end-end data stream
divided into *packets*

- ❑ user A, B packets *share* network resources
- ❑ each packet uses full link bandwidth
- ❑ resources used *as needed*

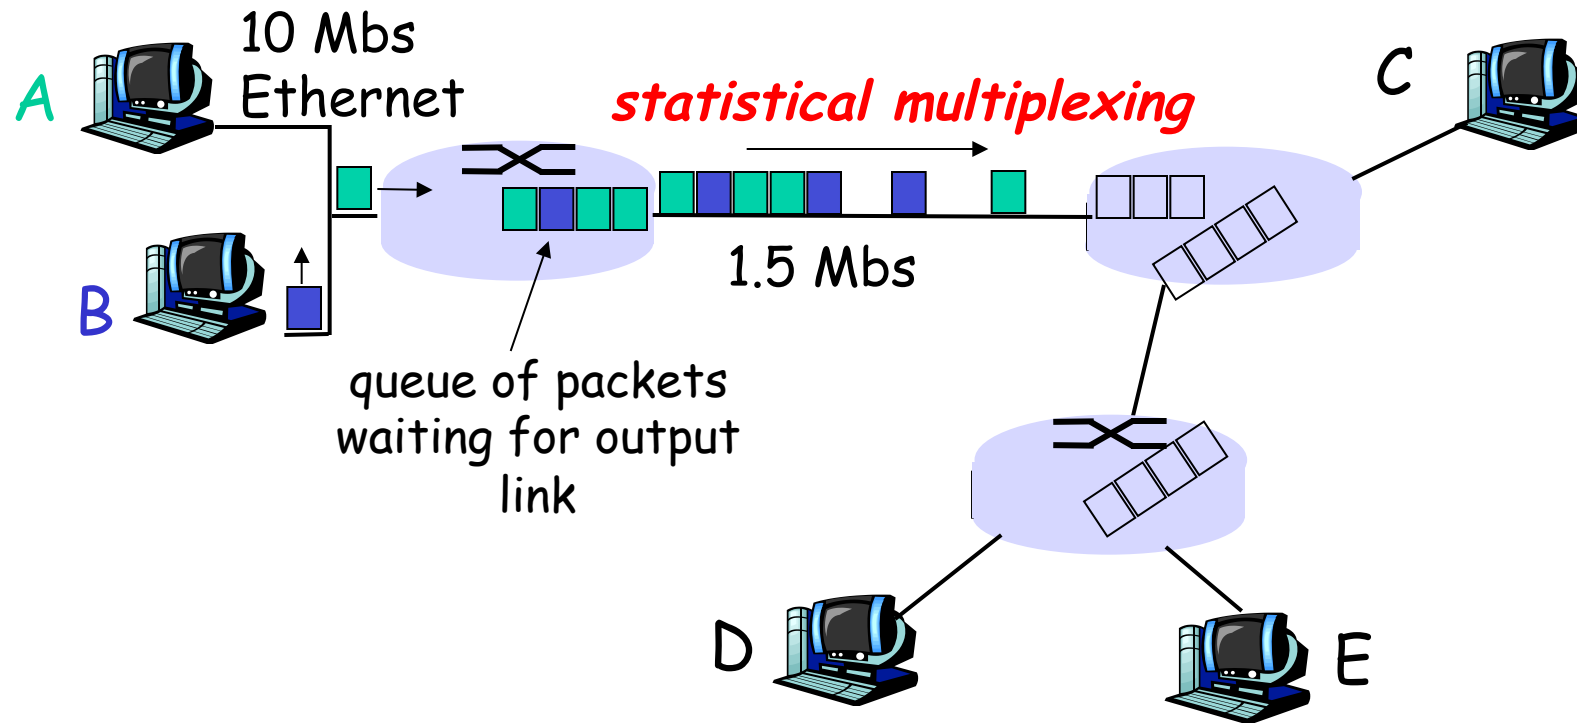

Bandwidth division into “pieces”
Dedicated allocation
Resource reservation

resource contention:

- ❑ aggregate resource demand can exceed amount available
- ❑ congestion: packets queue, wait for link use
- ❑ store and forward: packets move one hop at a time
 - Node receives complete packet before forwarding

Packet Switching: Statistical Multiplexing

Sequence of A & B packets does not have fixed pattern

➔ *statistical multiplexing*.

In TDM each host gets same slot in revolving TDM frame.

Packet switching versus circuit switching

Packet switching allows more users to use network!

- ❑ 1 Mbit link
- ❑ each user:
 - 100 kbps when “active”
 - active 10% of time
- ❑ circuit-switching:
 - 10 users
- ❑ packet switching:
 - with 35 users, probability > 10 active less than .0004

Source types

- Constant Bit Rate (e.g. encoded voice without silence suppression → voice packets have fixed size and are transmitted periodically. Required bit rate: 64Kbps)
- Variable Bit Rate (e.g. Video encoding, voice with silence suppression, file downloading etc.)
 - The bit rate varies with time
 - Source behavior characterized by min/max transmission rate, and average bit rate. Source burstiness = $\text{max bit rate} / \text{average bit rate}$.
 - Example: CBR ON/OFF

Packet switching versus circuit switching

Is packet switching a “slam dunk winner?”

- ❑ Great for bursty data
 - resource sharing
 - simpler, no call setup
- ❑ **Excessive congestion:** packet delay and loss
 - protocols needed for reliable data transfer, congestion control

Packet switching

- ❑ Perché dividere i messaggi trasmessi dall'applicazione in pacchetti di dimensione limitata.
 - Nelle prossime slides pro e contro....

Packet-switching: store-and-forward

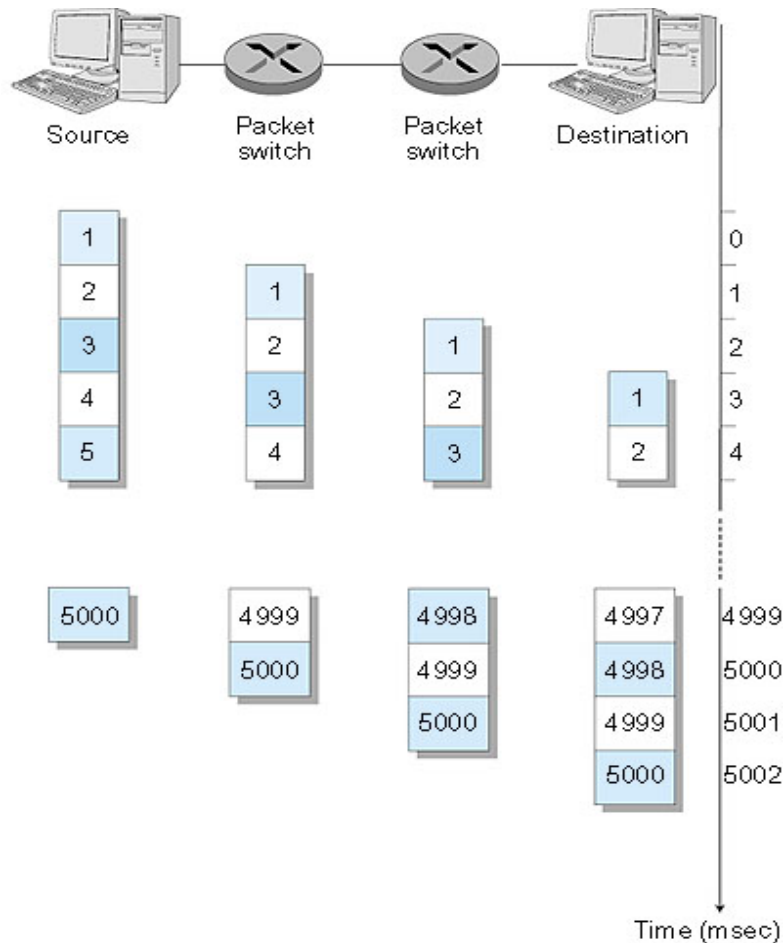

- ❑ Takes L/R seconds to transmit (push out) packet of L bits on to link or R bps
- ❑ Entire packet must arrive at router before it can be transmitted on next link: *store and forward*
- ❑ delay = $3L/R$

Example:

- ❑ $L = 7.5$ Mbit
- ❑ $R = 1.5$ Mbps
- ❑ delay = 15 sec
(only transmission delay considered here)

Packet Switching: Message Segmenting

Now break up the message into 5000 packets

- ❑ Each packet 1,500 bits
- ❑ 1 msec to transmit packet on one link
- ❑ *pipelining*: each link works in parallel
- ❑ Delay reduced from 15 sec to 5.002 sec

Message switching iff $\dim \text{pacchetti} = \dim. \text{messaggio originale applicativo}$

See packet-switching vs. message switching (no segmentation) and the effect of queueing delay through the Java applets on the Kurose-Ross website.

Effect of packet sizes

Packet format

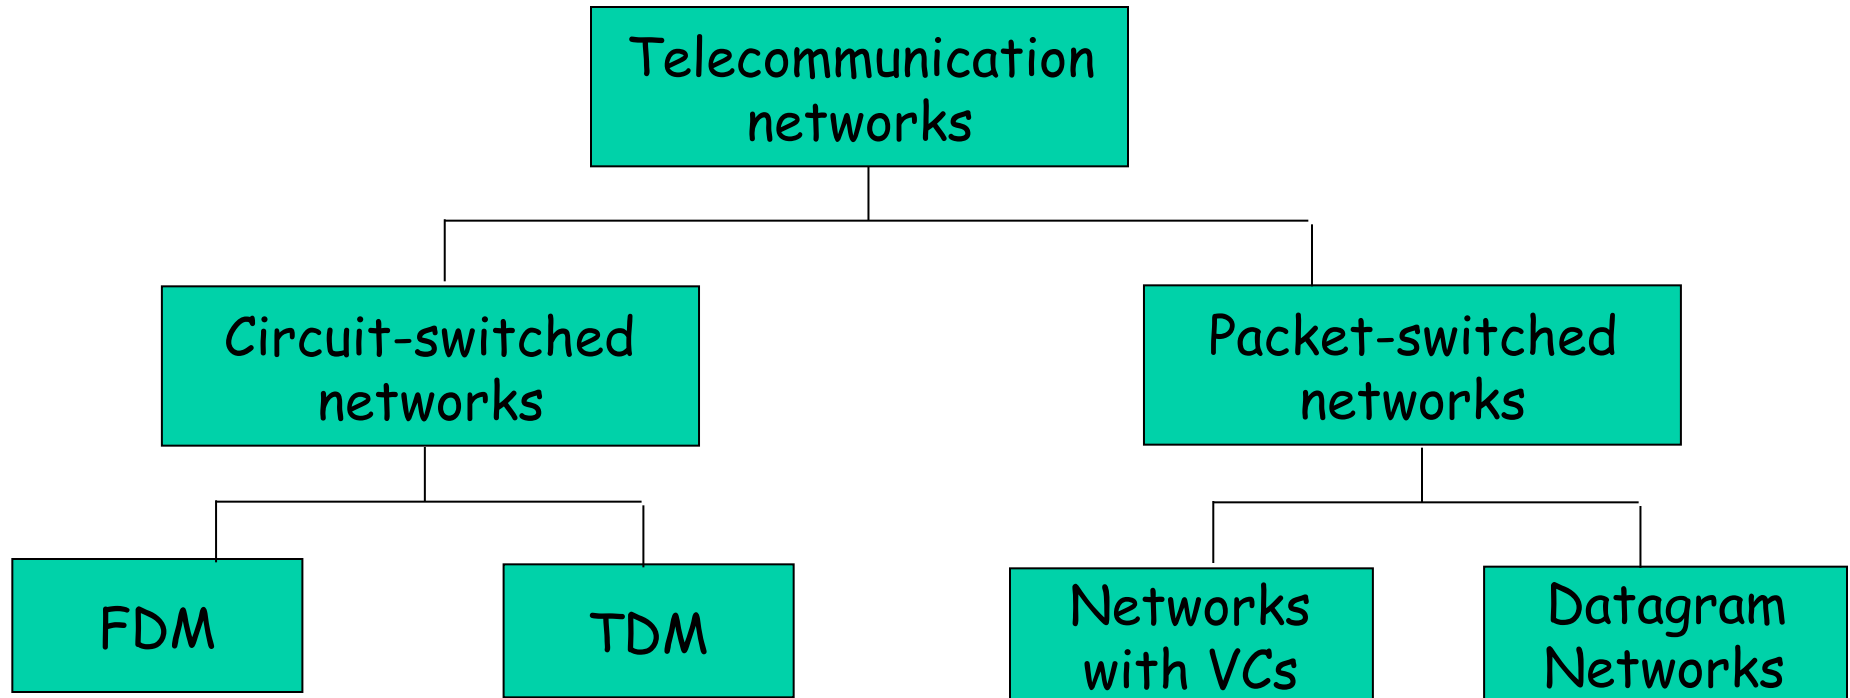

- ❑ A longer packet (more data transmitted in a single packet) leads to a lower overhead
- ❑ Longer packets result in a higher chance to be corrupted (critical especially for wireless transmission)
- ❑ When a packet is corrupted all the data are lost and need to be retransmitted
- ❑ Longer packets might decrease the parallelism of transmission

Packet-switched networks: forwarding

- ❑ **Goal:** move packets through routers from source to destination
 - we'll study several path selection (i.e. routing) algorithms (chapter 4)
- ❑ **datagram network:**
 - *destination address* in packet determines next hop
 - routes may change during session
 - analogy: driving, asking directions
- ❑ **virtual circuit network:**
 - each packet carries tag (virtual circuit ID), tag determines next hop
 - fixed path determined at *call setup time*, remains fixed thru call; VC share network resources
 - *routers maintain per-call state (the link on which a packet with a VC tag arriving to a given inbound link has to be forwarded and its VC tag on the next hop)*
 - Virtual circuit number changes from hop to hop. Each router has to map incoming interface, incoming VC # in outgoing interface, outgoing VC #
 - Why? (what would be the size of the VC number field and the complexity of the VC number assignment in case the same VC # had to be used over the whole path??)

Internet
L3 protocol:
IP

Network Taxonomy

- Datagram network is not either connection-oriented or connectionless.
- Internet provides both connection-oriented (TCP) and connectionless services (UDP) to apps.

Chapter 1: roadmap

1.1 What *is* the Internet?

1.2 Network edge

- end systems, access networks, links

1.3 Network core

- circuit switching, packet switching, network structure

1.4 Delay, loss and throughput in packet-switched networks

1.5 Protocol layers, service models

1.6 Networks under attack: security

1.7 History

A closer look at network structure:

- ❑ **network edge:**
applications and hosts
- ❑ **access networks, physical media:**
wired, wireless communication links
- ❑ **network core:**
 - ❖ interconnected routers
 - ❖ network of networks

The network edge:

□ end systems (hosts):

- run application programs
- e.g. Web, email
- at “edge of network”

□ client/server model

- ❖ client host requests, receives service from always-on server
- ❖ e.g. Web browser/server; email client/server

□ peer-peer model:

- ❖ minimal (or no) use of dedicated servers
- ❖ e.g. Skype, BitTorrent

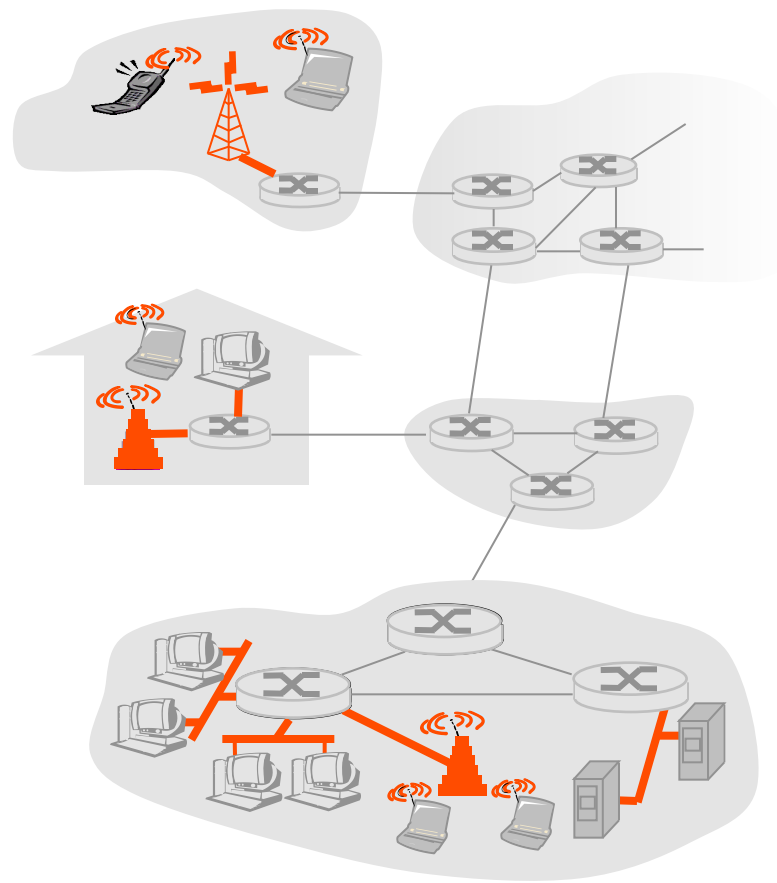

Access networks and physical media

Q: How to connect end systems to edge router?

- ❑ residential access nets
- ❑ institutional access networks (school, company)
- ❑ mobile access networks

Keep in mind:

- ❑ bandwidth (bits per second) of access network?
- ❑ shared or dedicated?

Transmission across a physical link

- ❑ **Bits:** propagate between transmitter and receiver
- ❑ **physical link:** what lies between transmitter & receiver
- ❑ **guided media:**
 - signals propagate in solid media: copper, fiber, coax
- ❑ **unguided media:**
 - signals propagate freely, e.g., radio

Transmission across a physical link

- ❑ Bit sequence modulates a suitable waveform which is sent across the link
 - How and which depends on the medium
- ❑ As the signal travels it experiences
 - **Attenuation** (absorption)
 - **Distortion** (limited bandwidth (frequency))
 - **Noise** (interference, thermal noise)
 - Influenced by medium, bit rate and distance
- ❑ Received sequence may be incorrect!!!

Codifica NRZ

❑ Codifica NRZ (Non Return to Zero)

Ogni bit ha associato un valore stabile per la sua intera durata (1: High; 0: Low)

Problemi di sincronizzazione del ricevitore (nessuna transizione nel caso di sequenze di zeri o di uni) → NRZ 5B6B o 4B5B

Codifica Manchester

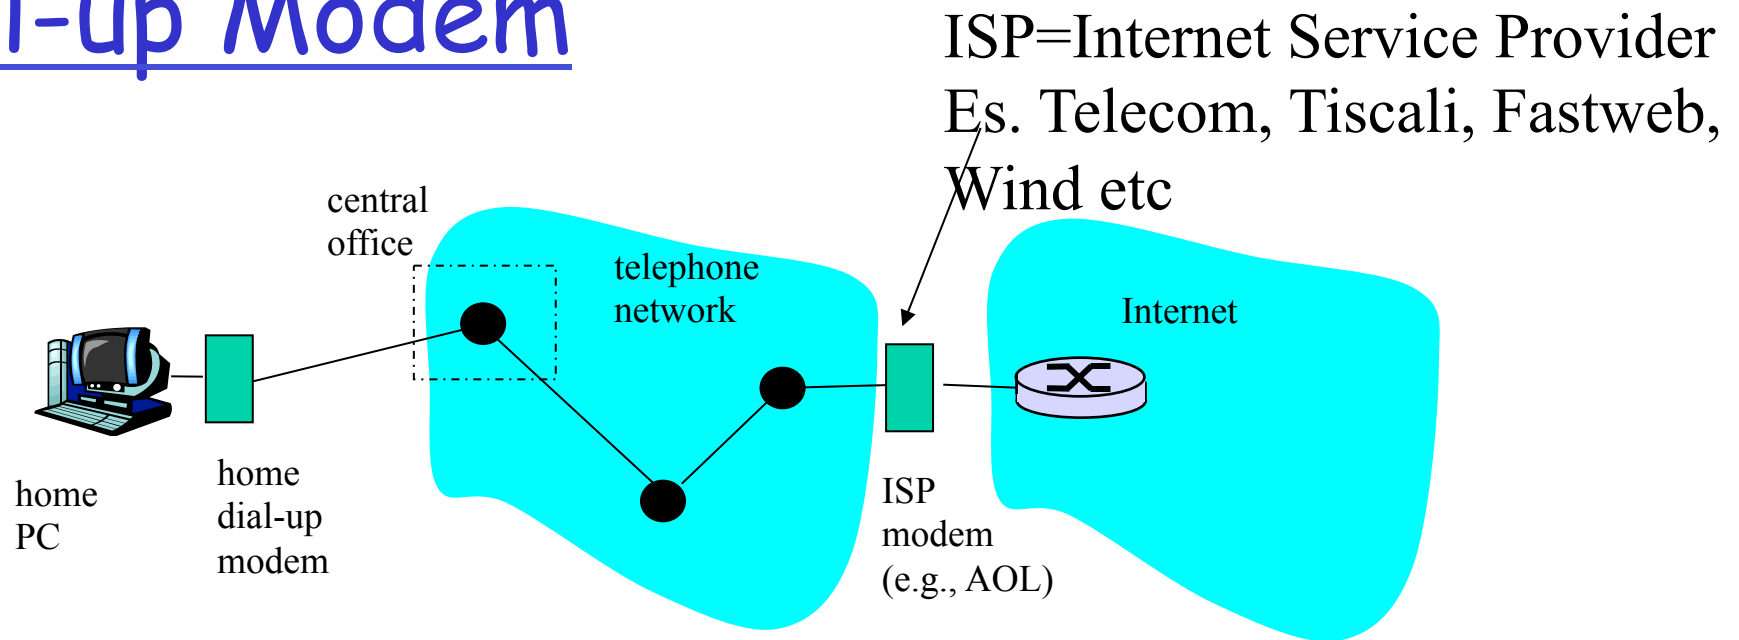

❑ Codifica Manchester

Una transizione basso-alto (codifica dello zero) o alto-basso (codifica del valore uno) in corrispondenza di ogni bit

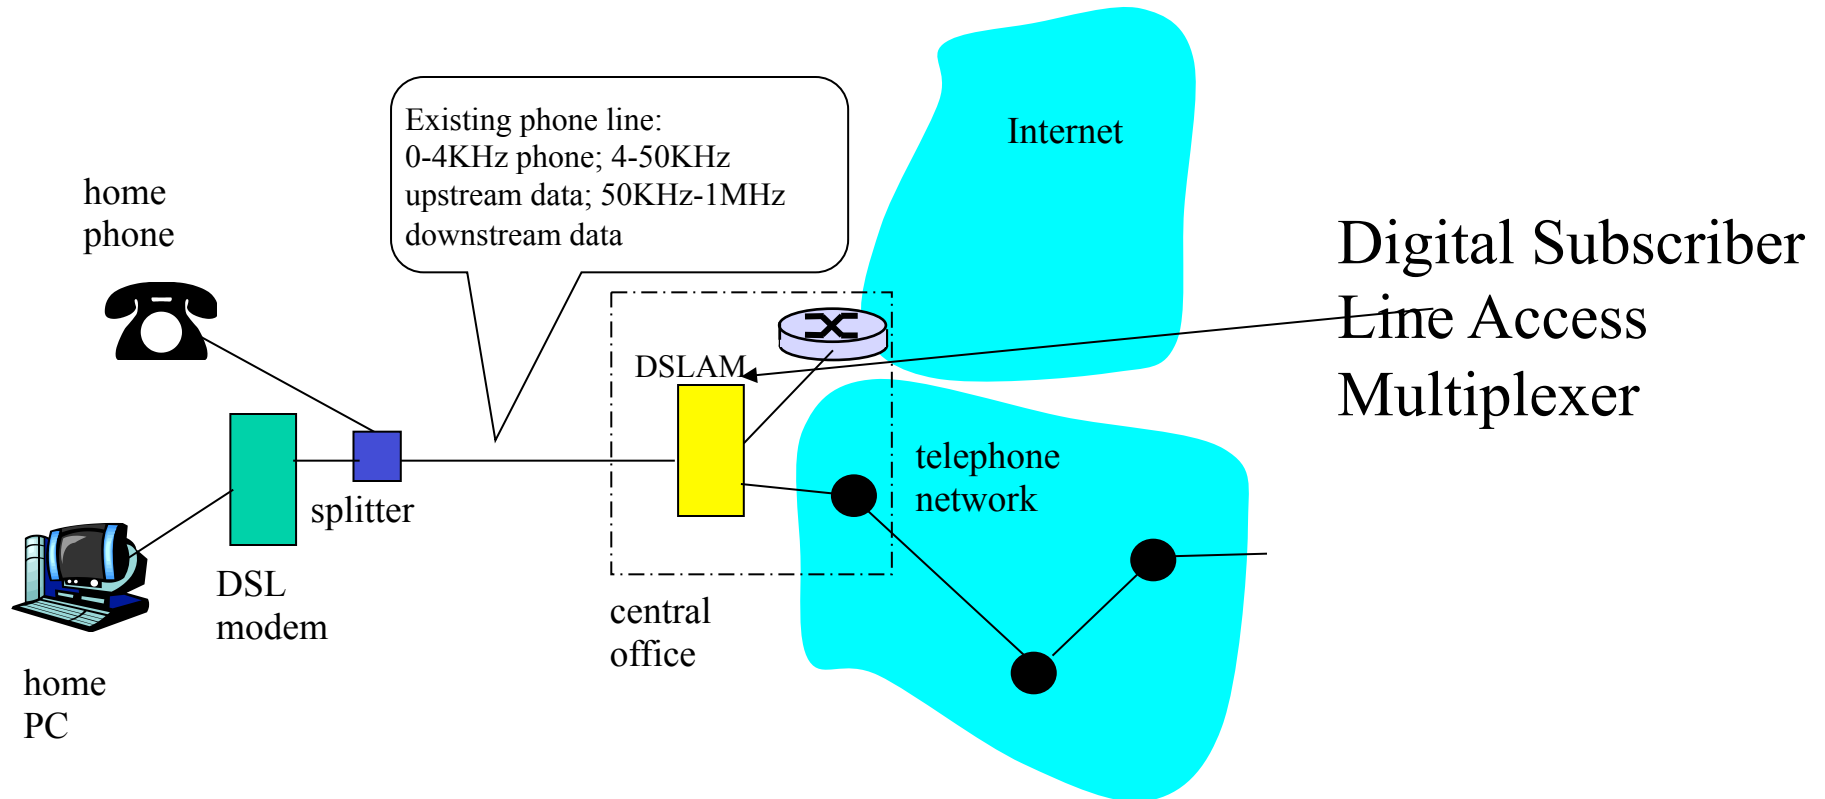

Usato in Ethernet 10Mbps e Token Ring

Dial-up Modem

- ❖ Uses existing telephony infrastructure
 - ❖ Home is connected to **central office**
- ❖ up to 56Kbps direct access to router (often less)
- ❖ Can't surf and phone at same time: not **"always on"**

Digital Subscriber Line (DSL)

- ❖ Also uses existing telephone infrastructure
- ❖ up to 1 Mbps upstream (today typically < 256 kbps)
- ❖ up to 8 Mbps downstream (today typically < 1 Mbps)
- ❖ dedicated physical line to telephone central office

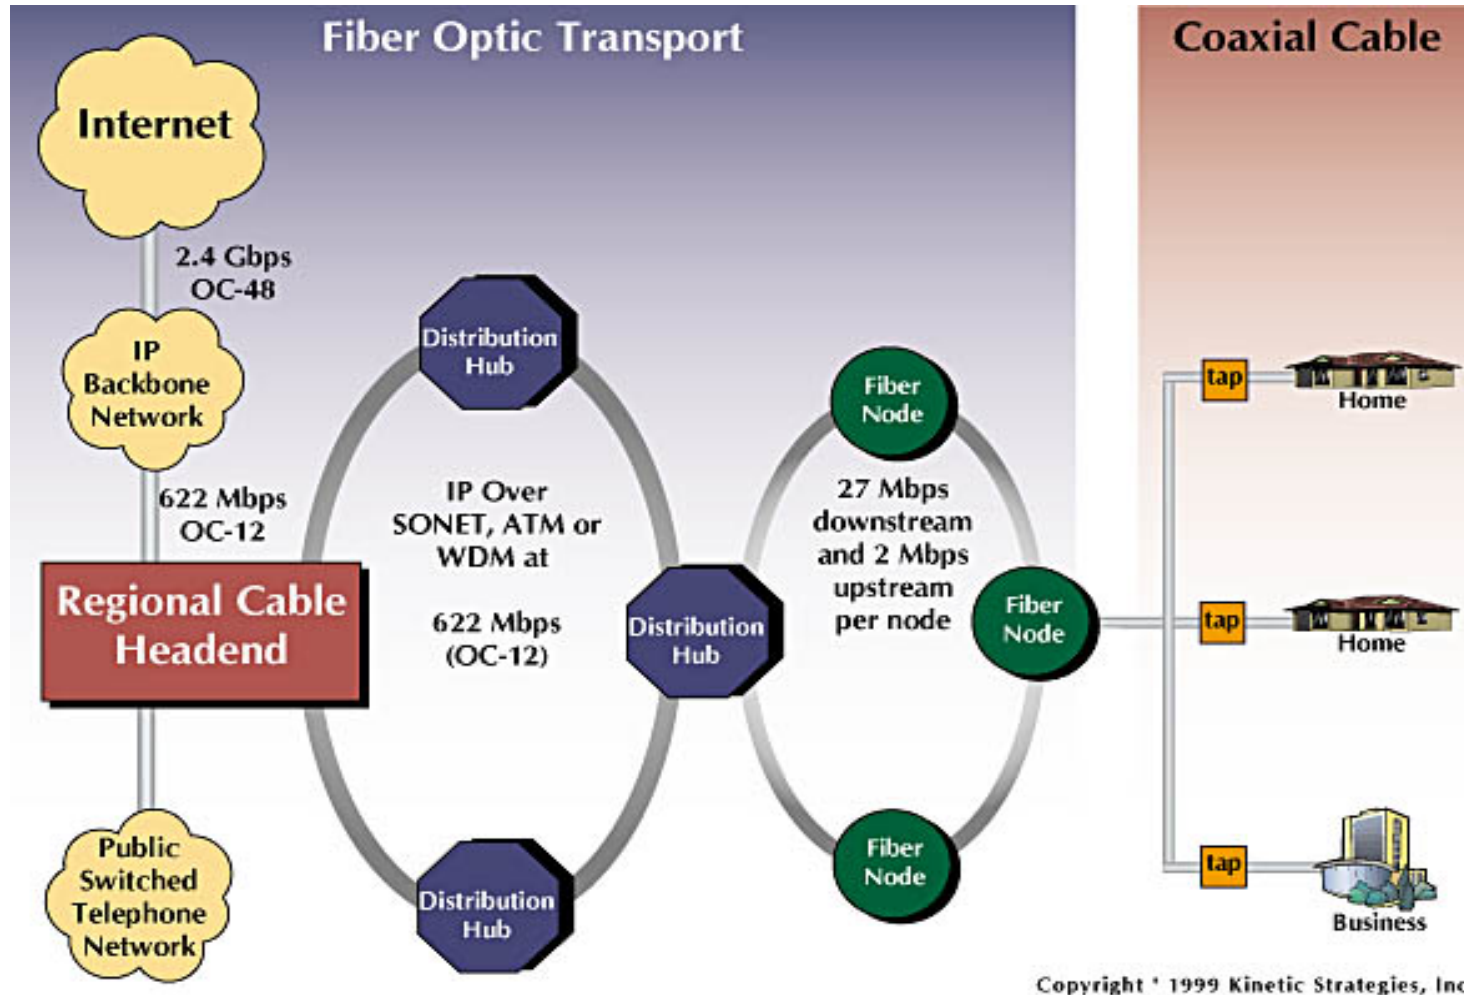

ADSL loops extender

- ❑ An **ADSL loop extender** or **ADSL repeater** is a device placed midway between the subscriber and central office by the telephone company to extend the distance and increase the channel capacity of their DSL connection.
- ❑ In some cases, service can now be established as far as 10 miles from the Central Office (factor of 2 improvement)

Residential access: cable modems

- ❑ Does not use telephone infrastructure
 - Instead uses cable TV infrastructure
- ❑ HFC: hybrid fiber coax
 - asymmetric: up to 30Mbps downstream, 2 Mbps upstream
- ❑ network of cable and fiber attaches homes to ISP router
 - homes share access to router
 - unlike DSL, which has dedicated access

Residential access: cable modems

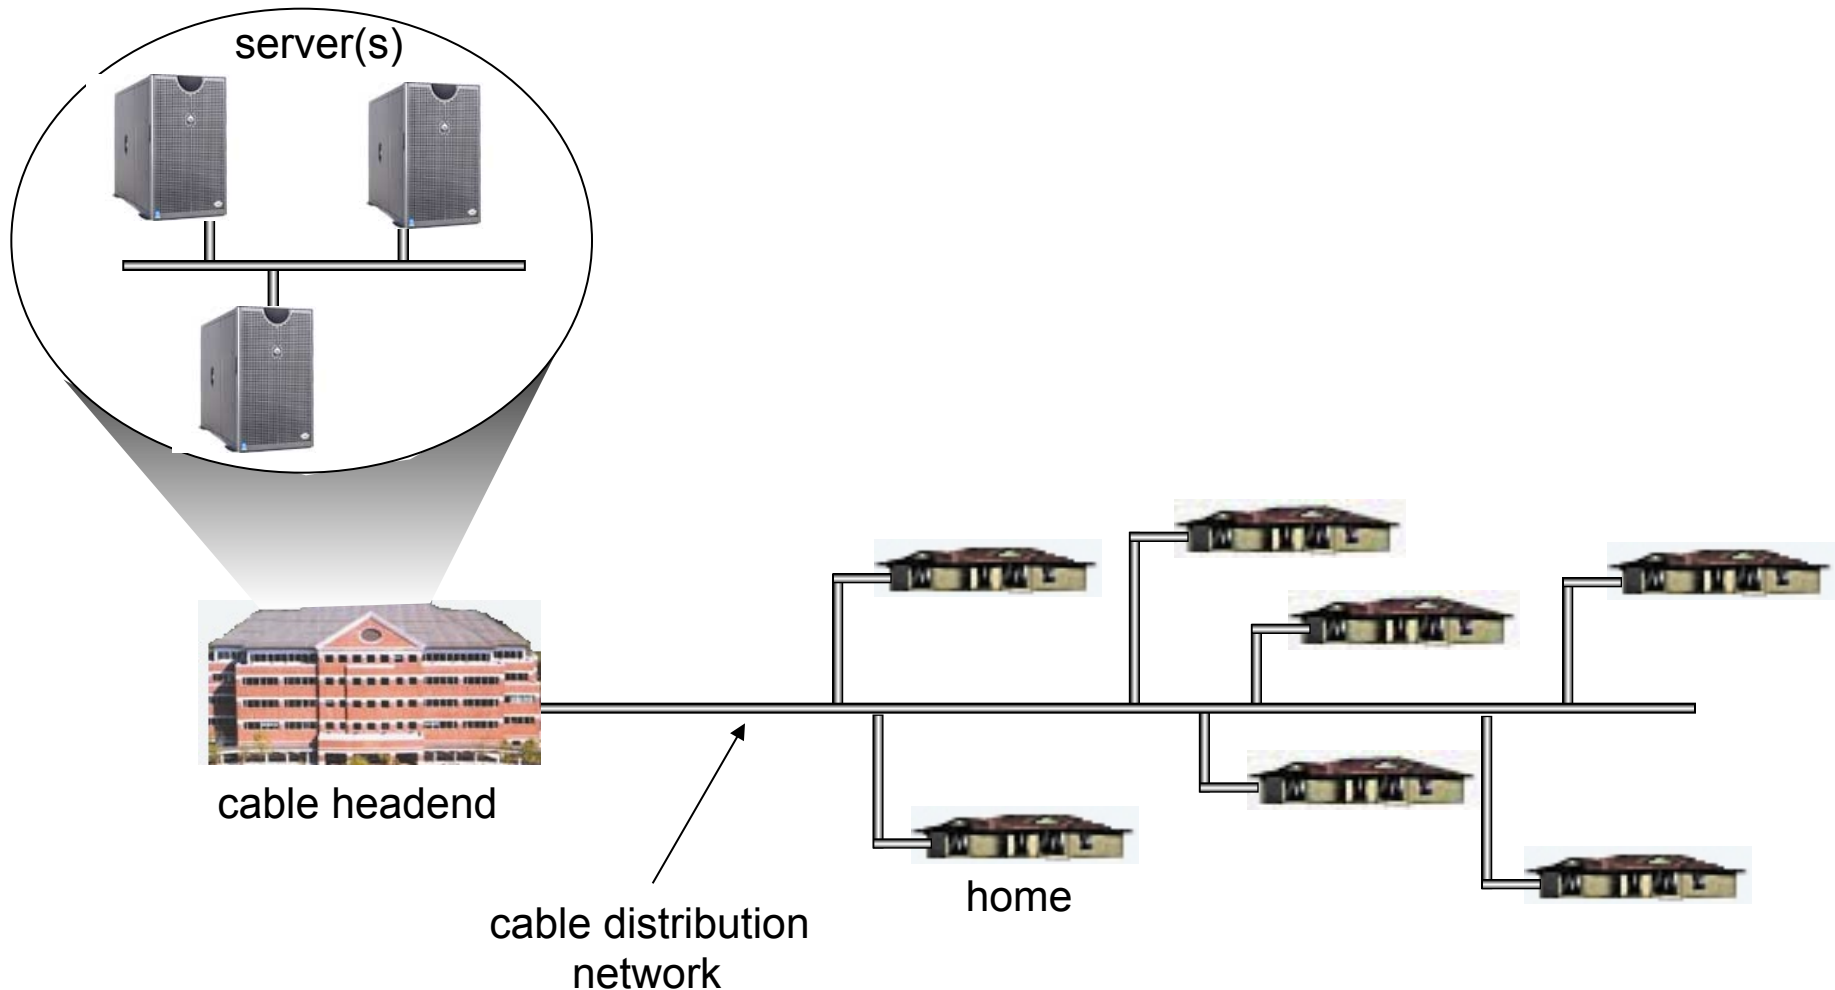

Cable Network Architecture: Overview

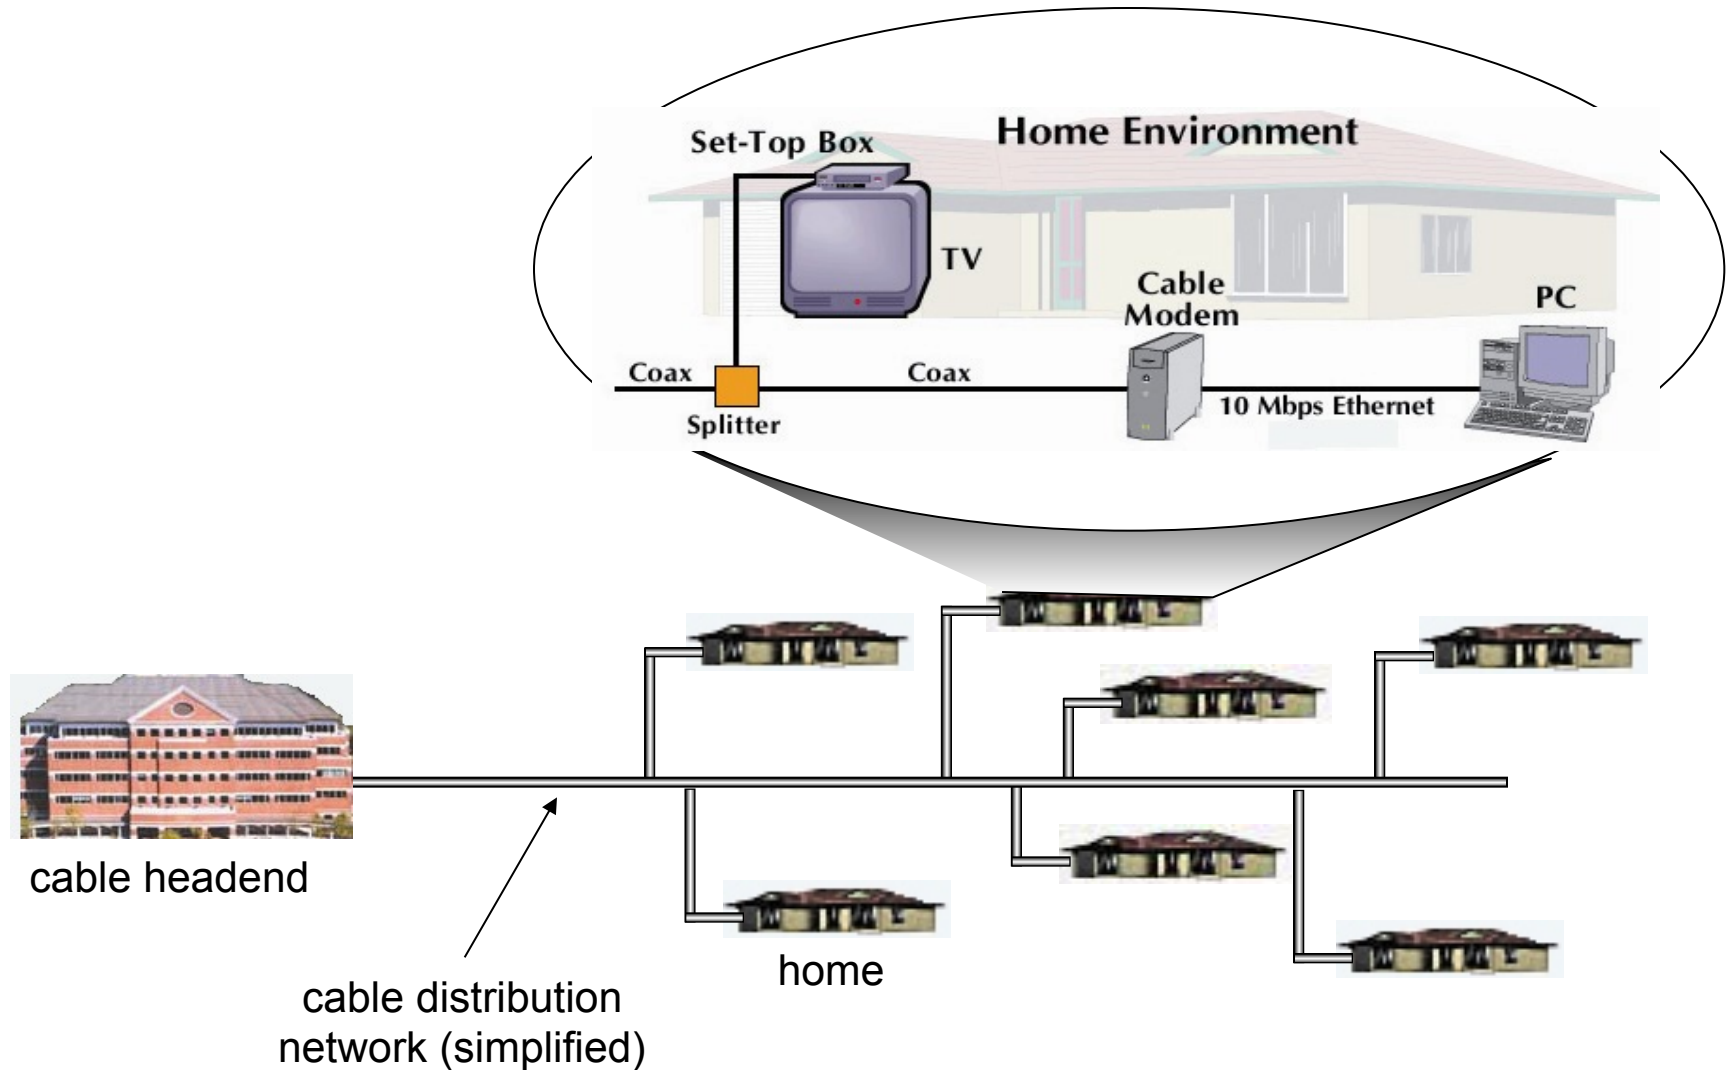

Typically 500 to 5,000 homes

Cable Network Architecture: Overview
