

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 *Message integrity*, authentication

8.4 Securing e-mail

8.5 Securing TCP connections: SSL

8.6 Network layer security: IPsec

8.7 Securing wireless LANs

8.8 Operational security: firewalls and IDS

Digital signatures

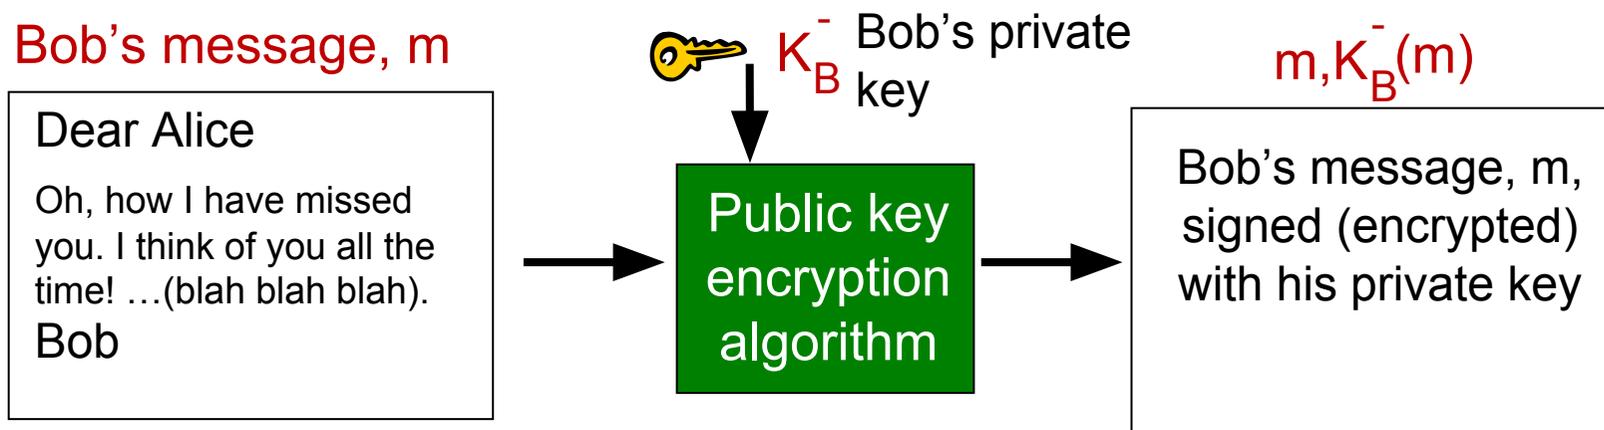

cryptographic technique analogous to hand-written signatures:

- ❖ sender (Bob) digitally signs document, establishing he is document owner/creator.
- ❖ *verifiable, nonforgeable*: recipient (Alice) can prove to someone that Bob, and no one else (including Alice), must have signed document

Digital signatures

simple digital signature for message m :

- ❖ Bob signs m by encrypting with his private key \bar{K}_B , creating “signed” message, $\bar{K}_B(m)$

Digital signatures

- ❖ suppose Alice receives msg m , with signature: $m, K_B^-(m)$
- ❖ Alice verifies m signed by Bob by applying Bob's public key K_B^+ to $K_B^-(m)$ then checks $K_B^+(K_B^-(m)) = m$.
- ❖ If $K_B^+(K_B^-(m)) = m$, whoever signed m must have used Bob's private key.

Alice thus verifies that:

- Bob signed m
- no one else signed m
- Bob signed m and not m'

non-repudiation:

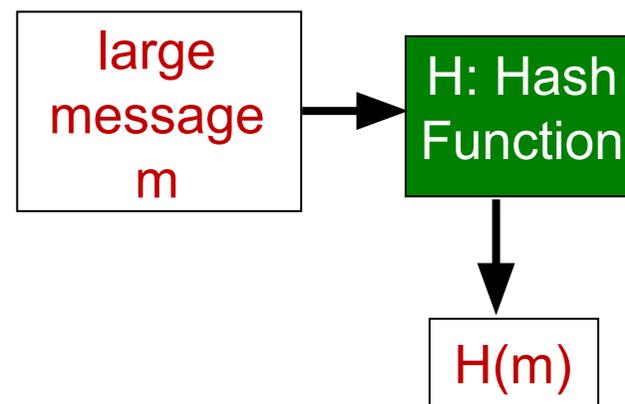

- Alice can take m , and signature $K_B^-(m)$ to court and prove that Bob signed m

Message digests

computationally expensive
to public-key-encrypt
long messages

goal: fixed-length, easy- to-
compute digital
“fingerprint”

- ❖ apply hash function H to m , get fixed size message digest, $H(m)$.

Hash function properties:

- ❖ many-to-1
- ❖ produces fixed-size msg digest (fingerprint)
- ❖ given message digest x , computationally infeasible to find m such that $x = H(m)$

Internet checksum: poor crypto hash function

Internet checksum has some properties of hash function:

- produces fixed length digest (16-bit sum) of message
- is many-to-one

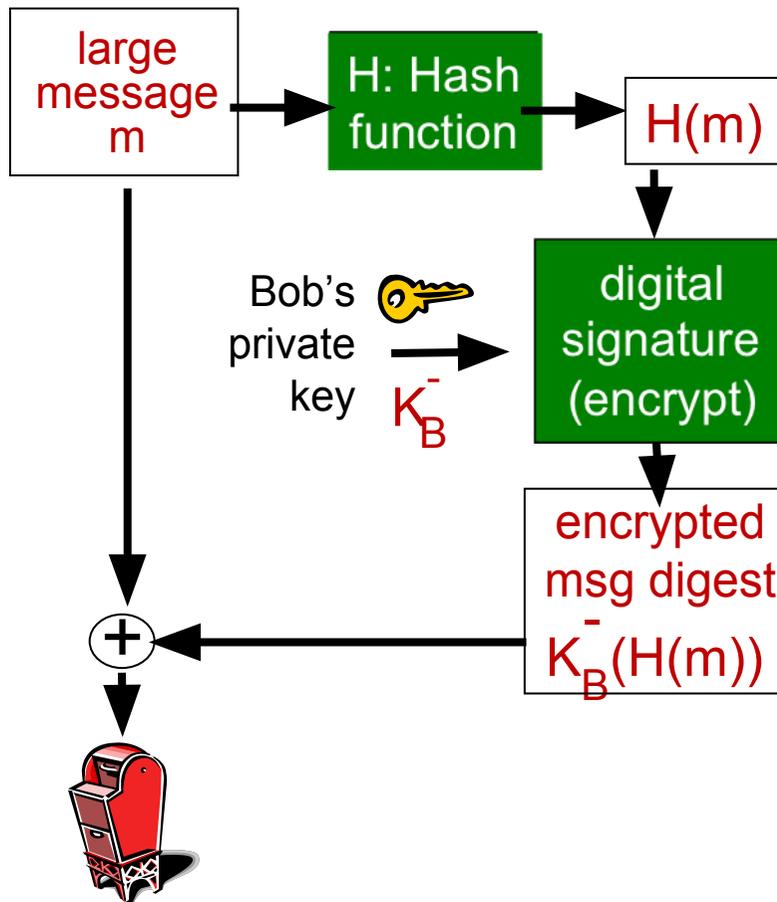

But given message with given hash value, it is easy to find another message with same hash value:

<u>message</u>	<u>ASCII format</u>	<u>message</u>	<u>ASCII format</u>
I O U 1	49 4F 55 31	I O U <u>9</u>	49 4F 55 <u>39</u>
0 0 . 9	30 30 2E 39	0 0 . <u>1</u>	30 30 2E <u>31</u>
9 B O B	39 42 D2 42	9 B O B	39 42 D2 42
<hr/>		<hr/>	
B2 C1 D2 AC			B2 C1 D2 AC

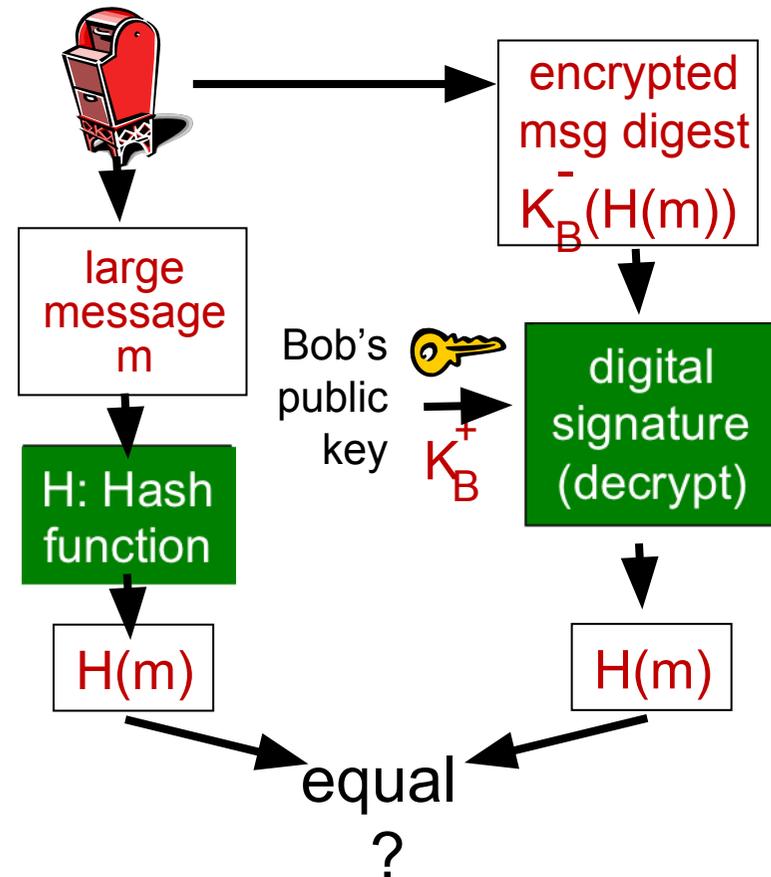

different messages — but identical checksums!

Digital signature = signed message digest

Bob sends digitally signed message:

Alice verifies signature, integrity of digitally signed message:

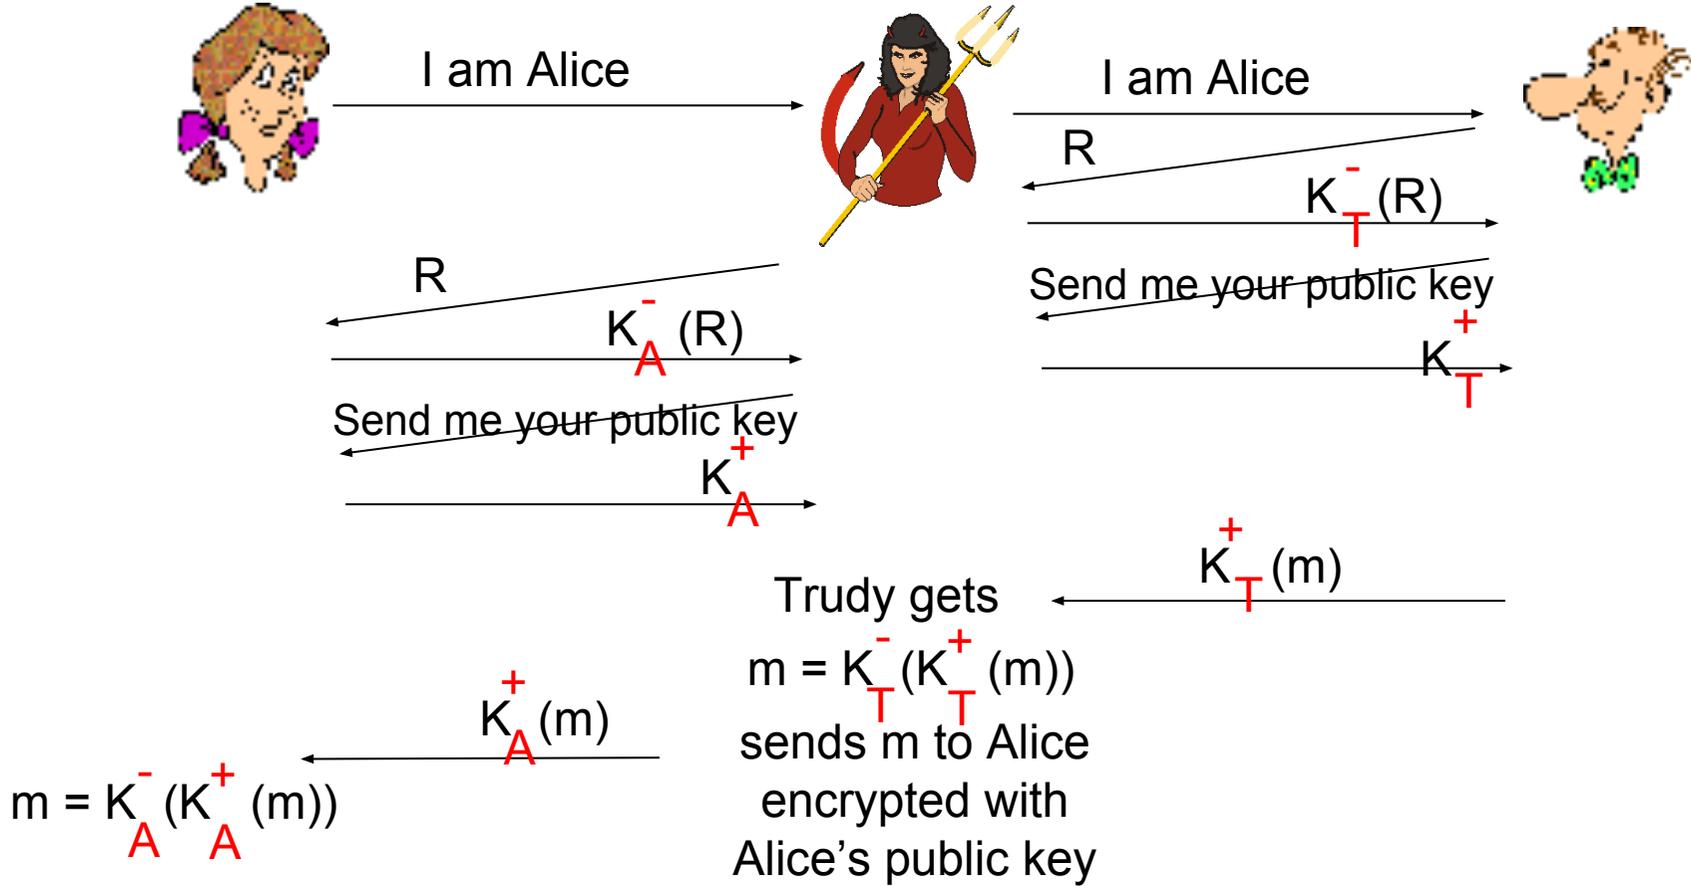

Hash function algorithms

- ❖ **MD5 hash function widely used (RFC 1321)**
 - computes 128-bit message digest in 4-step process.
 - arbitrary 128-bit string x , appears difficult to construct msg m whose MD5 hash is equal to x
- ❖ **SHA-1 is also used**
 - US standard [NIST, FIPS PUB 180-1]
 - 160-bit message digest

Recall: ap5.0 security hole

man (or woman) in the middle attack: Eve poses as Alice (to Bob) and as Bob (to Alice)

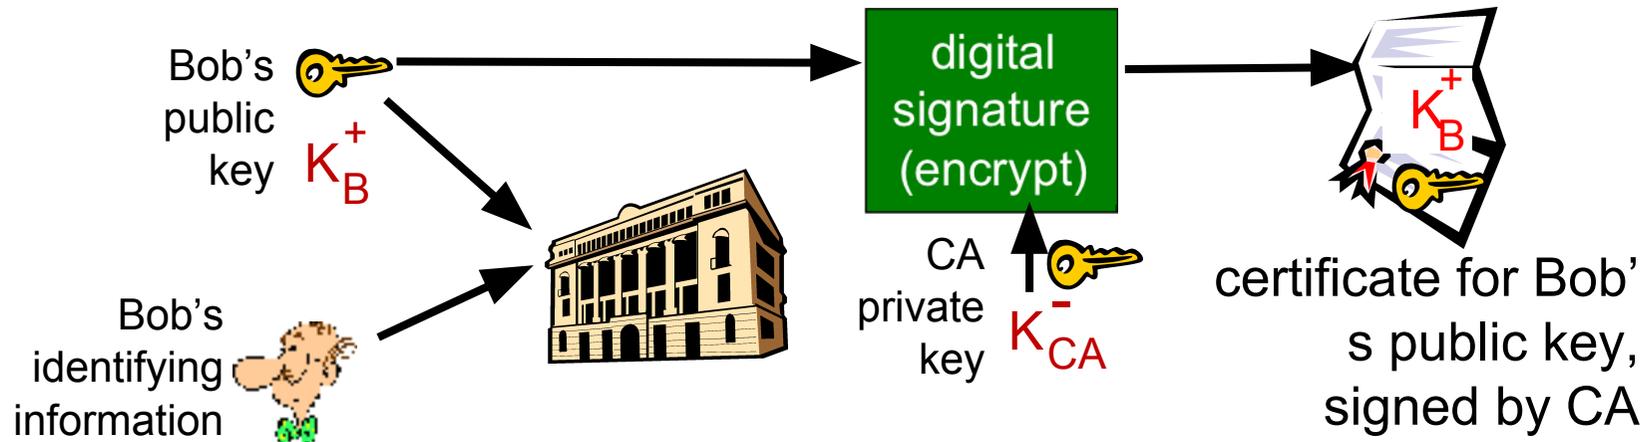

Public-key certification

- ❖ motivation: Eve plays pizza prank on Bob
 - Eve creates e-mail order:
Dear Pizza Store, Please deliver to me four pepperoni pizzas. Thank you, Bob
 - Eve signs order with her private key
 - Eve sends order to Pizza Store
 - Eve sends to Pizza Store her public key, but says it's Bob's public key
 - Pizza Store verifies signature; then delivers four pepperoni pizzas to Bob
 - Bob doesn't even like pepperoni

Certification authorities

- ❖ *certification authority (CA)*: binds public key to particular entity, E.
- ❖ E (person, router) registers its public key with CA.
 - E provides “proof of identity” to CA.
 - CA creates certificate binding E to its public key.
 - certificate containing E’s public key digitally signed by CA – CA says “this is E’s public key”

Certification authorities

- ❖ when Alice wants Bob's public key:
 - gets Bob's certificate (Bob or elsewhere).
 - apply CA's public key to Bob's certificate, get Bob's public key
